

TrendPilot

AI-filtered 15m trend-following signal bot with non-custodial wallet execution

The Problem & Our Solution

Trend bots on 15m charts fire too many false signals in choppy markets, eroding trader trust and consistency.

- Pure EMA/ADX trend signals whipsaw in choppy markets, creating frequent false breakouts.
- Traders want better signal quality but still want to control their own funds and execution.
- TrendPilot adds an ML classifier that filters out low-confidence trend signals before alerting users.
- Users keep full custody: every trade still requires their own Solana wallet signature.

How It Works

Signals are generated on 15m candles, filtered by ML, delivered via chat, and executed non-custodially on Solana.

- User connects their own Solana wallet to the bot; no funds are deposited anywhere.
- Engine computes EMA/ADX trend signals on BTC/ETH/SOL 15m candles using Pyth Network data.
- ML classifier scores each signal, ranking confidence to filter out likely false breakouts.
- Telegram/Discord bot delivers ranked, confidence-scored signals directly to the user.
- User approves a trade via Solana Actions/Blinks; wallet signs and Drift SDK executes on-chain.

Built with

Solana, Python, scikit-learn, Pyth Network, Solana Actions/Blinks, Drift SDK, Telegram Bot API

Why Now & What's Next

Solana Actions/Blinks make one-click non-custodial execution from chat apps simple, right when signal quality matters most.

- Solana Actions/Blinks enable one-click signed trades directly from Telegram and Discord.
- Pairing this with lightweight ML filtering raises signal quality without any custody risk.
- Next: expand the ML model with more features and a live retraining pipeline.
- Next: add portfolio-level risk management across BTC, ETH, and SOL positions.
- Next: launch a mobile app with push notifications and in-app execution.
